# PRODUCT REQUIREMENT DOCUMENT (PRD)

## UMHackathon 2026

## umhackathon@um.edu.my

**Team: MergeConflictSurvivor**

**Project Name: Commission Compass**

**Version: 1.0**

## 1. Project Overview

- **Problem Statement:** In Malaysia and the rest of the world, many individuals, businesses, and communities face challenges in making timely and informed decisions due to fragmented data, limited analytical capabilities, and reliance on manual or intuition-based processes. In our case we are targeting new freelancers and independent creators who may face problems in deciding a course of action towards a commission request due to the challenges.
- **Target Domain:** User-friendly, accurate and direct responses from an AI agent (z.ai).
- **Proposed Solution Summary:** We plan to use z.ai's ILMU-GLM-5.1 as our main logic model that can process an information, identify and summarize key points and concerns, generate questions for further understanding and the ability to search the answers to those questions. Then, once it has obtained enough information, the model shall compare the decisions and select the best option. Finally, the AI should be able to format its response to specific categories in a user-friendly manner,

## 2. Background & Business Objective

- **Background of the Problem:** Many freelancers across the globe face the same problem, demanding and unsatisfied consumers. New freelancers often fall into the trap of making ill-informed decisions due to manipulation by these consumers leading to financial loss. Another problem freelancers often face are sketchy offers from agencies that promise to "support" them but often end up using them for their own profits. This could lead to stagnant growth and even more negative impacts.
- **Importance of Solving This Issue:** Financial security for freelancers in what many views as a risky industry and encourages creative pursuits in individuals.
- **Strategic Fit / Impact:** This app may lead to the rise of freelancers or "solopreneurs". With the gig economy projected to make up over **50% of the US workforce by 2030**, a tool that professionalizes individual units of labour is perfectly timed for market expansion. This app can help boost confident in individuals to begin involving in freelancing or startups as the risk is much lower.

## 3. Product Purpose

**3.1. Main Goal of the System:** To provide an AI-assistant that can provide consultations on the best possible decisions during a commission-related dilemma.

### 3.2. Intended Users (Target Audience):

- Independent artists
- Independent musicians
- Independent Voice Actors/Actresses
- Independent Software Engineers
- Independent Cybersecurity Analysts

**4. System Functionalities**

**4.1. Description:** The system operates by accepting user input through our comprehensive and user-friendly UI to a backend server containing the GLM AI agent to process the input and return a specific response format. This format will then be shown through our UI after some behind-the-scenes formatting. Our app is available for cross-platform meaning it can be run on Mobile or Desktop devices.

**4.2. Key Functionalities:**

- Simple User-AI interaction
- Easy to create new chats
- Cross-platform

**4.3. AI Model & Prompt Design**

**4.3.1. Model Selection:** Do state the LLM used (Z AI GLM) along with justification why and what capabilities made it the right choice for the product's core functionalities.

4.3.2. **Prompting Strategy:** Describe your team's approach [e.g. zero-shot, few shot or multi-step agentic prompting]. So, explain the reason why the strategy chosen does fit your use case.

4.3.3. **Context & Input Handling**: Describe how the system that your team developed handles the unstructured or inputs that are oversized. So, what's the maximum input size your product does accept before it actually does truncation or chunking or rejection? So, what's going to happen to those inputs that exceed the limit?

4.3.4. **Fallback & Failure Behavior:** What does the developed product do when the model returns off-topic or unusable and most importantly hallucinated response? So, is there any mechanism for retrying, a human escalation path or even a graceful error state?

**5. User Stories & Use Cases**

- **User Stories:** *"I would like to ask a question whereby a customer asks if it was possible to reduce my commission price by 10% as they don't agree that a full body drawing should cost RM100. Is this valid?"*
- **Use Cases (Main Interactions):**
    - User enters the question into the chat text box
    - User creates a new chat
    - User replies to chat

**6. Assumptions & Constraints**

- **LLM Cost Constraint:** Token cost should be between 400-500 tokens, and we keep it manageable by caching them if user replies.
- **Technical Constraints:** Backend server that contains the API agent may need a more costly host. Furthermore, communication between backend and frontend may cause the response to appear late for users.
- **Performance Constraints:** To gain the most accurate data, the system may take a while to process the tokens which could slow output.
- **User Input:** [e.g. The model is unable to generate without human prompts and is not ready for production so requires human approval.]

**9. Risks & Questions Throughout Development**

- **Previous context understanding:** How will the AI track previous responses and prompts to generate coherent responses?
- **Incorrect output risk:** How to ensure the information AI gets can be correctly validated?
